Abstract

- Main aim of this Mini Project is to illustrate the concepts of color combination and usage of OpenGL library.
- > Our project demonstrates what happens when the primary colors i.e Red, Green and Blue are combined.
- All the permutations and combinations of colors are taken care of.
- > We have used input devices like mouse and key board to interact with program

System specifications

> SOFTWARE REQUIREMENTS:

- MICROSOFT VISUAL C++
- OPENGL

HARDWARE REQUIREMENT:

- GRAPHICS SYSTEM,
- Pentium P4 with 256 of Ram(Min)

Introduction to openGL

As a software interface for graphics hardware, OpenGL's main purpose is to render two- and three-dimensional objects into a frame buffer.

These objects are described as sequences of vertices or pixels.

OpenGL performs several processing steps on this data to convert it to pixels to

3 Dept. of Computer Science & Engineering.

form the final desired image in the frame buffer.

OpenGL Fundamentals

This section explains some of the concepts inherent in OpenGL.

Primitives and Commands

OpenGL draws primitives—points, line segments, or polygons—subject to several selectable modes.

You can control modes independently of each other; that is, setting one mode doesn't affect whether other modes are set .Primitives are specified, modes are set, and other OpenGL operations are described by issuing commands in the form of function calls.

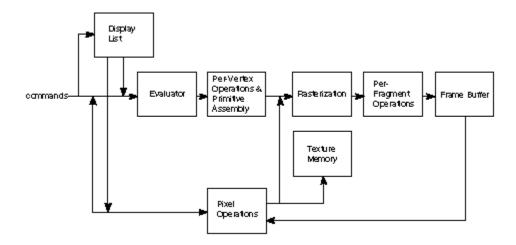

Primitives are defined by a group of one or more vertices. A vertex defines a point, an endpoint of a line, or a corner of a polygon where two edges meet. Data is associated with a vertex, and each vertex and its associated data are processed independently, in order, and in the same way. The type of clipping depends on which primitive the group of vertices represents.

Commands are always processed in the order in which they are received, although there may be an indeterminate delay before a command takes effect. This means that each primitive is drawn completely before any subsequent command takes effect. It also means that state-querying commands return data that's consistent with complete execution of all previously issued OpenGL commands.

Basic OpenGL Operation

The figure shown below gives an abstract, high-level block diagram of how OpenGL processes data. In the diagram, commands enter from the left and proceed through what can be thought of as a processing pipeline. Some commands specify geometric objects to be drawn, and others control how the objects are handled during the various processing stages.

Figure . OpenGL Block Diagram

As shown by the first block in the diagram, rather than having all commands proceed immediately through the pipeline, you can choose to accumulate some of them in a display list for processing at a later time.

Rasterization produces a series of frame buffer addresses and associated values using a two-dimensional description of a point, line segment, or polygon.

Each fragment so produced is fed into the last stage,

per-fragment operations, which performs the final operations on the data before it's stored as pixels in the frame buffer. These operations include conditional updates to the frame buffer based on incoming and previously stored z-value s (for z-buffering) and blending of incoming pixel colors with stored colors, as well as masking and other logical operations on pixel values.

All elements of OpenGL state, including the contents of the texture memory and even of the frame buffer, can be obtained by an OpenGL application.

Implementation

This program is implemented using various openGL functions which are shown below.

Various functions used in this program.

- > glutInit(): interaction between the windowing system and OPENGL is initiated
- > glutInitDisplayMode(): used when double buffering is required and depth information is required

- > glutCreateWindow(): this opens the OPENGL window and displays the title at top of the window
- glutInitWindowSize(): specifies the size of the window
- glutInitWindowPosition(): specifies the position of the window in screen co-ordinates
- glutKeyboardFunc(): handles normal ascii symbols
- glutSpecialFunc(): handles special keyboard keys
- glutReshapeFunc(): sets up the callback function for reshaping the window
- glutIdleFunc(): this handles the processing of the background
- glutDisplayFunc(): this handles redrawing of the window
- > glutMainLoop(): this starts the main loop, it never returns
- > glViewport(): used to set up the viewport
- > glVertex3fv(): used to set up the points or vertices in three dimensions
- glColor3fv(): used to render color to faces
- glFlush(): used to flush the pipeline

- > glutPostRedisplay(): used to trigger an automatic redrawal of the object
- > glMatrixMode(): used to set up the required mode of the matrix
- > glLoadIdentity(): used to load or initialize to the identity matrix
- > glTranslatef(): used to translate or move the rotation centre from one point to another in three dimensions
- > glRotatef(): used to rotate an object through a specified rotation angle

Interaction with program

- This program includes interaction through keyboard.
- S → Start the Project
- R → Toggle Red Light
- G → Toggle Green Light
- B → Toggle Blue Light
- Q-> Quit

Source Code

/*An Interactive Program to create 3d objects*/

```
static float green1=0;

```

OUTPUT OF THE PROGRAM

Conclusions

The project "Color Combination" clearly demonstrates the use of OpenGL functions and what happens when primary colors are mixed.

Finally we conclude that this program clearly illustrate the color combination using openGL and has been completed successfully and is ready to be demonstrated.

Bibliography

WE HAVE OBTAINED INFORMATION FROM MANY RESOURCES TO DESIGN AND IMPLEMENT OUR PROJECT SUCCESSIVELY. WE HAVE ACQUIRED MOST OF THE KNOWLEDGE FROM RELATED WEBSITES. THE FOLLOWING ARE SOME OF THE
